(54) Title: GnRH-LEUKOTOXIN CHIMERAS**(57) Abstract**

New immunological carrier systems, DNA encoding the same, and the use of these systems, are disclosed. The carrier systems include chimeric proteins which comprise a leukotoxin polypeptide fused to a selected GnRH multimer which consists essentially of at least one repeating GnRH decapeptide sequence, or at least one repeating unit of a sequence corresponding to at least one epitope of a selected GnRH molecule. Under the invention, the selected GnRH sequences may all be the same, or may correspond to different derivatives, analogues, variants or epitopes of GnRH so long as the GnRH sequences are capable of eliciting an immune response. The leukotoxin functions to increase the immunogenicity of the GnRH multimer fused thereto.

GnRH-LEUKOTOXIN CHIMERASDescriptionTechnical Field

10 The present invention relates generally to immunological carrier systems. More particularly, the invention pertains to leukotoxin-GnRH chimeras including more than one copy of a GnRH polypeptide, which demonstrate enhanced immunogenicity as compared to the
15 immunogenicity of GnRH polypeptides alone.

Background of the Invention

 In vertebrates, synthesis and release of the two gonadotrophic hormones, luteinizing hormone (LH) and
20 follicle stimulating hormone (FSH), are regulated by a polypeptide referred to as Gonadotropin releasing hormone (GnRH) (formerly designated LHRH). Accordingly, one approach to fertility control in an animal population is to reduce the levels of GnRH, such as by immunization
25 against GnRH, which effects a reduction in the levels of LH and FSH and the concomitant disruption of estrous cycles and spermatogenesis. See e.g., Adams et al., *J. Anim. Sci.* (1990) 68:2793-2802.

 In particular, early studies of the GnRH
30 molecule have shown that it is possible to raise antisera in response to repeated injections of synthetic GnRH peptides (Arimura et al., *Endocrinology* (1973) 93(5):1092-1103). Further, antibodies to GnRH have been raised in a number of species by chemical conjugation of
35 GnRH to a suitable carrier and administration of the

conjugate in an appropriate adjuvant (Carelli et al.,
Proc. Natl. Acad. Sci. (1982) 79:5392-5395). Recombinant
fusion proteins comprising GnRH or GnRH-analogues have
also been described for use in peptide vaccines for the
5 immunological castration or inhibition of reproductive
function of various domesticated and farm animals (Meloan
et al., Vaccine (1994) 12(8):741-746; Hoskinson et al.,
Aust. J. Biotechnol. (1990) 4:166-170; and International
Publication Nos. WO 92/19746, published 12 November 1992;
10 WO 91/02799, published 7 March 1991; WO 90/11298,
published 4 October 1990 and WO 86/07383, published 18
December 1986).

However, attempts have fallen short of
providing adequate immunological sterilization products
15 due to the poor immunogenicity of GnRH peptides and due
to the fact that chemical conjugation protocols are
difficult to control, rendering substantially
heterogenous and poorly-defined GnRH conjugates.
Further, peptide vaccines based on GnRH have met with
20 limited success in providing uniform effects on
individual animal subjects even after repeated
vaccination. In this regard, prior GnRH constructs have
failed to provide a uniformly successful immunological
sterilization vaccine product due to the fact that GnRH
25 is a small, "self" molecule that is not normally
recognized by a subject's immune system, rendering the
molecule poorly immunogenic and inherently unable to
induce a significant immune response against endogenous
GnRH.

30 It is generally recognized that the
immunogenicity of viral antigens, small proteins or
endogenous substances may be significantly increased by
producing immunogenic forms of those molecules comprising
multiple copies of selected epitopes. In this regard,
35 constructs based on two or four repeats of peptides 9-21

of herpes simplex virus type 1 glycoprotein D (Ploeg et al., *J. Immuno. Methods* (1989) 124:211-217), two to six repeats of the antigenic circumsporozoite tetrapeptide NPNA of *Plasmodium falciparum* (Lowell et al., *Science* 5 (1988) 240:800-802), two or four copies of the major immunogenic site of VP1 of foot-and-mouth disease virus (Broekhuijsen et al., *J. gen. Virol.* (1987) 68:3137-3143) and tandem repeats of a GnRH-like polypeptide (Meloan et al., *Vaccine* (1994) 12(8):741-746), have been shown to be 10 effective in increasing the immunogenicity of those molecules.

Furthermore, small proteins or endogenous substances may also be conjugated to a suitable carrier in order to elicit a significant immune response in a 15 challenged host. Suitable carriers are generally polypeptides which include antigenic regions of a protein derived from an infectious material such as a viral surface protein, or a carrier peptide sequence. These carriers serve to non-specifically stimulate T helper 20 cell activity and to help direct antigen to antigen presenting cells for processing and presentation of the peptide at the cell surface in association with molecules of the major histocompatibility complex (MHC).

Several carrier systems have been developed for 25 this purpose. For example, small peptide antigens are often coupled to protein carriers such as keyhole limpet haemocyanin (Bittle et al., *Nature* (1982) 298:30-33), tetanus toxoid (Muller et al., *Proc. Natl. Acad. Sci. U.S.A.* (1982) 79:569-573), ovalbumin, and sperm whale 30 myoglobin, to produce an immune response. These coupling reactions typically result in the incorporation of several moles of peptide antigen per mole of carrier protein. Although presentation of the peptide antigen in multiple copies generally enhances immunogenicity, 35 carriers may elicit strong immunity not relevant to the

peptide antigen and this may inhibit the immune response to the peptide vaccine on secondary immunization (Schutze et al, *J. Immun.* (1985) 135:2319-2322).

Antigen delivery systems have also been based
5 on particulate carriers. For example, preformed particles have been used as platforms onto which antigens can be coupled and incorporated. Systems based on proteosomes (Lowell et al., *Science* (1988) 240:800-802),
immune stimulatory complexes (Morein et al., *Nature*
10 (1984) 308:457-460), and viral particles such as HBsAg (Neurath et al., *Mol. Immunol.* (1989) 26:53-62) and rotavirus inner capsid protein (Redmond et al., *Mol. Immunol.* (1991) 28:269-278) have been developed.

Carrier systems have also been devised using
15 recombinantly produced chimeric proteins that self assemble into particles. For example, the yeast retrotransposon, Ty, encodes a series of proteins that assemble into virus like particles (Ty-VLPs; Kingsman, S. M., and A. J. Kingsman *Vacc.* (1988) 6:304-306). Foreign
20 genes have been inserted into the TyA gene and expressed in yeast as a fusion protein. The fusion protein retains the capacity to self assemble into particles of uniform size.

Other chimeric protein particles have been
25 examined such as HBsAg, (Valenzuela et al., *Bio/Technol.* (1985) 3:323-326; U.S. Patent No. 4,722,840; Delpeyroux et al., *Science* (1986) 233:472-475), Hepatitis B core antigen (Clarke et al., *Vaccines 88* (Ed. H. Ginsberg, et al., 1988) pp. 127-131), Poliovirus (Burke et al., *Nature*
30 (1988) 332:81-82), and Tobacco Mosaic Virus (Haynes et al., *Bio/Technol.* (1986) 4:637-641). However, these carriers are restricted in their usefulness by virtue of the limited size of the active agent which may be
35 inserted into the structural protein without interfering with particle assembly.

Finally, chimeric systems have been devised using a *Pasteurella haemolytica* leukotoxin (LKT) polypeptide fused to a selected antigen. See, e.g., International Publication Nos. WO 93/08290, published 29 April 1993 and WO 92/03558, published 5 March 1992, as well as U.S. Patent Nos. 5,238,823 and 5,273,889. Inclusion of a LKT carrier portion in a peptide antigen chimera supplies enhanced immunogenicity to the chimera by providing T-cell epitopes having broad species reactivity, thereby eliciting a T-cell dependent immune response in immunized subjects. In this regard, inducement of adequate T-cell help is essential in the generation of an immune response to the peptide antigen portion of the chimera, particularly where the antigen is an endogenous molecule. However, the use of a leukotoxin polypeptide carrier in combination with multiple epitopes of the GnRH peptide has not heretofore been described.

Disclosure of the Invention

The present invention is based on the construction of novel gene fusions between the *P. haemolytica* leukotoxin gene, variants thereof, and nucleotide sequences encoding multiple GnRH polypeptides. These constructs produce chimeric proteins that display surprisingly enhanced immunogenicity when compared to the immunologic reaction elicited by administration of GnRH alone.

Thus in one embodiment, the present invention is directed to a chimeric protein comprising a leukotoxin polypeptide fused to a multimer consisting essentially of more than one selected GnRH polypeptide, whereby the leukotoxin portion of the chimera acts to increase the immunogenicity of the GnRH polypeptide. More particularly, the GnRH multimer may correspond to more than one copy of a selected GnRH polypeptide or epitope,

or multiple tandem repeats of a selected GnRH polypeptide or epitope. Further, the GnRH multimer may be located at the carboxyl or amino terminals, or at sites internal to the leukotoxin polypeptide. The GnRH multimer may also
5 correspond to a molecule of the general formula GnRH-X-GnRH wherein X is selected from the group consisting of a peptide linkage, an amino acid spacer group and $[\text{GnRH}]_n$, where n is greater than or equal to 1, and further wherein "GnRH" may comprise any GnRH polypeptide.

10 Also disclosed are vaccine compositions comprising the chimeric proteins and a pharmaceutically acceptable vehicle, and methods for presenting a selected GnRH multimer to a host subject comprising administering an effective amount of the subject vaccine compositions.

15 In another embodiment, the subject invention is directed to DNA constructs encoding the chimeric proteins. The DNA constructs comprise a first nucleotide sequence encoding a leukotoxin polypeptide operably linked to a second nucleotide sequence encoding more than
20 one copy of a GnRH epitope.

In yet another embodiment, the subject invention is directed to expression cassettes comprised of (a) the DNA constructs above and (b) control sequences that direct the transcription of the construct whereby
25 the constructs can be transcribed and translated in a host cell.

In another embodiment, the invention is directed to host cells transformed with these expression cassettes.

30 Another embodiment of the invention provides a method of producing a recombinant polypeptide. The method comprises (a) providing a population of host cells described above and (b) culturing the population of cells under conditions whereby the polypeptide encoded by the
35 expression cassette is expressed.

These and other embodiments of the present invention will readily occur to those of ordinary skill in the art in view of the disclosure herein.

5 Brief Description of the Figures

Figures 1A and 1B show the nucleotide sequences and amino acid sequences of the GnRH constructs used in the chimeric leukotoxin-GnRH polypeptide gene fusions. Figure 1A depicts GnRH-1 which includes a single copy of
10 a GnRH decapeptide; Figure 1B depicts GnRH-2 which includes four copies of a GnRH decapeptide when n=1, and eight copies of GnRH when n=2, etc.

Figure 2 depicts the structure of Plasmid pAA352 wherein tac is the hybrid trp::lac promoter from
15 *E. coli*; bla represents the β -lactamase gene (ampicillin resistance); ori is the ColE1-based plasmid origin of replication; lktA is the *P. haemolytica* leukotoxin structural gene; and lacI is the *E. coli* lac operon repressor. The direction of transcription/translation of
20 the leukotoxin gene is indicated by the arrow. The size of each component is not drawn to scale.

Figures 3-1 through 3-9 show the nucleotide sequence and predicted amino acid sequence of leukotoxin 352 (LKT 352). Both the structural gene for LKT 352 and
25 the sequences of the flanking vector regions are shown.

Figure 4 shows the structure of Plasmid pCB113 carrying a leukotoxin-GnRH (LKT-GnRH) gene fusion.

Figures 5-1 through 5-8 show the nucleotide sequence and predicted amino acid sequence of the LKT-GnRH chimeric protein from pCB113. The nucleotide
30 sequence and predicted amino acid sequence of the LKT-GnRH chimeric protein from pCB112 are identical to the sequences of the chimeric protein derived from pCB113 except that the sequence for multiple copy GnRH was
35 inserted twice as described above in regard to Figure 4.

Figure 6 shows the structure of Plasmid pCB111 carrying a leukotoxin-GnRH (LKT-GnRH) gene fusion.

Figures 7-1 through 7-5 show the nucleotide sequence and predicted amino acid sequence of the LKT-GnRH chimeric protein from pCB111. The nucleotide sequence and predicted amino acid sequence of the LKT-GnRH chimeric protein from pCB114 are identical to the sequences of the chimeric protein derived from pCB111 except that the sequence for multiple copy GnRH was inserted twice as described above in regard to Figure 6.

Figure 8 shows the nucleotide sequence and predicted amino acid sequence of the blunt end fusion point of the truncated leukotoxin gene of plasmid pCB111 (Figure 8-2), where an internal DNA fragment (of approximately 1300 bp in length) was removed from LKT 352 by digestion with the restriction enzymes BstB1 and NaeI (Figure 8-1).

Detailed Description

The practice of the present invention will employ, unless otherwise indicated, conventional techniques of molecular biology, microbiology, virology, recombinant DNA technology, and immunology, which are within the skill of the art. Such techniques are explained fully in the literature. See, e.g., Sambrook, Fritsch & Maniatis, Molecular Cloning: A Laboratory Manual; DNA Cloning, Vols. I and II (D.N. Glover ed.) ; Oligonucleotide Synthesis (M.J. Gait ed.); Nucleic Acid Hybridization (B.D. Hames & S.J. Higgins eds.); Animal Cell Culture (R.K. Freshney ed.); Immobilized Cells and Enzymes (IRL press); B. Perbal, A Practical Guide to Molecular Cloning; the series, Methods In Enzymology (S. Colowick and N. Kaplan eds., Academic Press, Inc.); and Handbook of Experimental Immunology, Vols. I-IV (D.M. Weir and C.C. Blackwell eds., Blackwell Scientific Publications).

A. Definitions

In describing the present invention, the following terms will be employed, and are intended to be defined as indicated below.

5 The term "Gonadotropin releasing hormone" or "GnRH" refers to a decapeptide secreted by the hypothalamus which controls release of both luteinizing hormone (LH) and follicle stimulating hormone (FSH) in vertebrates (Fink, G., *British Medical Bulletin* (1979) 10 35:155-160). The amino acid sequence of GnRH is highly conserved among vertebrates, and especially in mammals. In this regard, GnRH derived from most mammals including human, bovine, porcine and ovine GnRH (formerly designated LHRH) has the amino acid sequence pyroGlu-His-15 Trp-Ser-Tyr-Gly-Leu-Arg-Pro-Gly-NH₂ (Murad et al., *Hormones and Hormone Antagonists*, in The Pharmacological Basis of Therapeutics, Sixth Edition (1980) and Seeburg et al., *Nature* (1984) 311:666-668).

 As used herein a "GnRH polypeptide" includes a 20 molecule derived from a native GnRH sequence, as well as recombinantly produced or chemically synthesized GnRH polypeptides having amino acid sequences which are substantially homologous to native GnRH and which remain immunogenic, as described below. Thus, the term 25 encompasses derivatives and analogues of GnRH including any single or multiple amino acid additions, substitutions and/or deletions occurring internally or at the amino or carboxy terminuses of the peptide. Accordingly, under the invention, a "GnRH polypeptide" 30 includes molecules having the native sequence, molecules such as that depicted in Figure 1A (having an N-terminal Gln residue rather than a pyroGlu residue), and molecules with other amino acid additions, substitutions and/or deletions which retain the ability to elicit formation of 35 antibodies that cross react with naturally occurring

GnRH. Particularly contemplated herein are repeated sequences of GnRH polypeptides such as in the oligomer depicted in Figure 1B (wherein each of the selected GnRH polypeptides comprises a N-terminal Gln substitution, and further wherein every other GnRH polypeptide comprises an Asp residue substitution at position 2). Epitopes of GnRH are also captured by the definition.

The term "epitope" refers to the site on an antigen or hapten to which a specific antibody molecule binds. Since GnRH is a very small molecule, the identification of epitopes thereof which are able to elicit an antibody response is readily accomplished using techniques well known in the art. See, e.g., Geysen et al. *Proc. Natl. Acad. Sci. USA* (1984) 81:3998-4002 (general method of rapidly synthesizing peptides to determine the location of immunogenic epitopes in a given antigen); U.S. Patent No. 4,708,871 (procedures for identifying and chemically synthesizing epitopes of antigens); and Geysen et al., *Molecular Immunology* (1986) 23:709-715 (technique for identifying peptides with high affinity for a given antibody).

As used herein the term "T-cell epitope" refers to a feature of a peptide structure which is capable of inducing T-cell immunity towards the peptide structure or an associated hapten. In this regard, it is accepted in the art that T-cell epitopes comprise linear peptide determinants that assume extended conformations within the peptide-binding cleft of MHC molecules, (Unanue et al., *Science* (1987) 236:551-557). Conversion of polypeptides to MHC class II-associated linear peptide determinants (generally between 5 - 14 amino acids in length) is termed "antigen processing" which is carried out by antigen presenting cells (APCs). More particularly, a T-cell epitope is defined by local features of a short peptide structure, such as primary

amino acid sequence properties involving charge and hydrophobicity, and certain types of secondary structure, such as helicity, that do not depend on the folding of the entire polypeptide. Further, it is believed that short peptides capable of recognition by helper T-cells are generally amphipathic structures comprising a hydrophobic side (for interaction with the MHC molecule) and a hydrophilic side (for interacting with the T-cell receptor), (Margalit et al., *Computer Prediction of T-cell Epitopes*, New Generation Vaccines Marcel-Dekker, Inc, ed. G.C. Woodrow et al., (1990) pp. 109-116) and further that the amphipathic structures have an α -helical configuration (see, e.g., Spouge et al., *J. Immunol.* (1987) 138:204-212; Berkower et al., *J. Immunol.* (1986) 136:2498-2503).

Hence, segments of proteins which include T-cell epitopes can be readily predicted using numerous computer programs. (See e.g., Margalit et al., *Computer Prediction of T-cell Epitopes*, New Generation Vaccines Marcel-Dekker, Inc, ed. G.C. Woodrow et al., (1990) pp. 109-116). Such programs generally compare the amino acid sequence of a peptide to sequences known to induce a T-cell response, and search for patterns of amino acids which are believed to be required for a T-cell epitope.

An "immunogenic protein" or "immunogenic amino acid sequence" is a protein or amino acid sequence, respectively, which elicits an immunological response in a subject to which it is administered. Under the invention, a "GnRH immunogen" refers to a GnRH molecule which, when introduced into a host subject, stimulates an immune response. In this regard, a GnRH immunogen includes a multimer corresponding to more than one selected GnRH polypeptide sequence; and, more particularly, to a multimer having either multiple or tandem repeats of selected GnRH polypeptide sequences,

multiple or tandem repeats of selected GnRH epitopes, or any conceivable combination thereof.

5 An "immunological response" to an antigen or vaccine is the development in the host of a cellular and/or antibody-mediated immune response to the composition or vaccine of interest. Usually, such a response includes but is not limited to one or more of the following effects; the production of antibodies, B cells, helper T cells, suppressor T cells, and/or cytotoxic T
10 cells and/or $\gamma\delta$ T cells, directed specifically to an antigen or antigens included in the composition or vaccine of interest. An immunological response can be detected using any of several immunoassays well known in the art.

15 The term "leukotoxin polypeptide" or "LKT polypeptide" intends a polypeptide which includes at least one T-cell epitope and is derived from a protein belonging to the family of molecules characterized by the carboxy-terminus consensus amino acid sequence
20 Gly-Gly-X-Gly-X-Asp (Highlander et al., *DNA* (1989) 8:15-28), where X is Lys, Asp, Val or Asn. Such proteins include, among others, leukotoxins derived from *P. haemolytica* and *Actinobacillus pleuropneumoniae*, as well as *E. coli* alpha hemolysin (Strathdee et al., *Infect. Immun.* (1987) 55:3233-3236; Lo, *Can. J. Vet. Res.* (1990) 54:S33-S35; Welch, *Mol. Microbiol.* (1991) 5:521-528).
25 This family of toxins is known as the "RTX" family of toxins (Lo, *Can. J. Vet. Res.* (1990) 54:S33-S35). In addition, the term "leukotoxin polypeptide" refers to a
30 leukotoxin polypeptide which is chemically synthesized, isolated from an organism expressing the same, or recombinantly produced. Furthermore, the term intends an immunogenic protein having an amino acid sequence substantially homologous to a contiguous amino acid
35 sequence found in the particular native leukotoxin

molecule. Thus, the term includes both full-length and partial sequences, as well as analogues. Although native full-length leukotoxins display leukotoxic activity, the term "leukotoxin" also intends molecules which remain
5 immunogenic yet lack the cytotoxic character of native leukotoxins. The nucleotide sequences and corresponding amino acid sequences for several leukotoxins are known. See, e.g., U.S. Patent Nos. 4,957,739 and 5,055,400; Lo et al., *Infect. Immun.* (1985) 50:667-67; Lo et al.,
10 *Infect. Immun.* (1987) 55:1987-1996; Strathdee et al., *Infect. Immun.* (1987) 55:3233-3236; Highlander et al., *DNA* (1989) 8:15-28; Welch, *Mol. Microbiol.* (1991) 5:521-528. In the chimeras produced according to the present invention, a selected Leukotoxin polypeptide sequence
15 imparts enhanced immunogenicity to a fused GnRH multimer by providing, among other things, T-cell epitopes comprising small peptide segments in the range of five to fourteen amino acids in length which are capable of complexing with MHC class II molecules for presentation
20 to, and activation of, T-helper cells. As discussed further below, these T-cell epitopes occur throughout the leukotoxin molecule and are thought to be concentrated in the N-terminus portions of leukotoxin, i.e., between amino acid residues 1 to 199.

25 As used herein, a leukotoxin polypeptide "which lacks leukotoxic activity" refers to a leukotoxin polypeptide as described above which lacks significant cytotoxicity as compared to a native, full-length leukotoxin (such as the full-length *P. haemolytica*
30 leukotoxin described in U.S. Patent Nos. 5,055,400 and 4,957,739) yet still retains immunogenicity and at least one T-cell epitope. Leukotoxin polypeptides can be tested for leukotoxic activity using any of several known assays such as the lactate dehydrogenase release assay,
35 described by Korzeniewski et al., *Journal of*

Immunological Methods 64:313-320, wherein cytotoxicity is measured by the release of lactate dehydrogenase from bovine neutrophils. A molecule is identified as leukotoxic if it causes a statistically significant release of lactate dehydrogenase when compared to a control non-leukotoxic molecule.

Under the invention, construction of LKT-GnRH chimeras comprising leukotoxin polypeptides which lack leukotoxic activity provides several important benefits. Initially, a leukotoxin polypeptide which lacks leukotoxic activity is desirable since the injection of an active toxin into a subject can result in localized cell death (PMNs and macrophages) and, in turn, cause a severe inflammatory response and abscess at the injection site. In this regard, leukotoxic activity resulting in the killing of macrophages may lead to reduced antigen presentation and hence a suboptimal immune response. The removal of the cytotoxic portion as found in the non-leukotoxic LKT polypeptides used in producing the fusion proteins of the invention also results in a truncated LKT gene which is capable of being expressed at much higher levels than full-length LKT. Further, the use of non-leukotoxic LKT polypeptides in the fusions constructed under the present invention which retain sufficient T-cell antigenicity reduces the overall amount of leukotoxin-GnRH antigen which needs to be administered to a host subject to yield a sufficient B-cell response to the selected GnRH polypeptides. Particular examples of immunogenic leukotoxin polypeptides which lack leukotoxic activity include LKT 352 and LKT 111 which are described in greater detail below.

By "LKT 352" is meant a protein which is derived from the *lktA* gene present in plasmid pAA352 (Figure 2, ATCC Accession No. 68283). The nucleotide sequence and corresponding amino acid sequence of this

gene are described in International Publication No. WO91/15237 and are shown in Figure 3. The gene encodes a truncated leukotoxin, having 931 amino acids and an estimated molecular weight of around 99 kDa, which lacks the cytotoxic portion of the molecule. The truncated gene thus produced is expressed at much higher levels than the full-length molecule (more than 40% of total cell protein versus less than 1% of total cell protein for the full-length form) and is more easily purified. Under the invention, the derived LKT 352 is not necessarily physically derived from the sequence present in plasmid pAA352. Rather, it may be generated in any manner, including for example, by chemical synthesis or recombinant production. In addition, the amino acid sequence of the protein need only be substantially homologous to the depicted sequence. Thus, sequence variations may be present so long as the LKT polypeptide functions to enhance the immunogenicity of antigen with which it is associated yet also lacks leukotoxic activity.

By "LKT 111" is meant a leukotoxin polypeptide which is derived from gene present in plasmid pCB111 (Figure 6, ATCC Accession No. 69748). The nucleotide sequence of this gene and the corresponding amino acid sequence are shown in Figure 7. The gene encodes a shortened version of leukotoxin which was developed from the recombinant leukotoxin gene present in plasmid pAA352 (Figure 2, ATCC Accession No. 68283) by removal of an internal DNA fragment of approximately 1300 bp in length. The LKT 111 polypeptide has an estimated molecular weight of 52 kDa (as compared to the 99 kDa LKT 352 polypeptide), but retains portions of the N-terminus from LKT 352 containing T-cell epitopes which are necessary for sufficient T-cell immunogenicity and portions from the C-terminus from LKT 352 containing convenient

restriction sites for use in producing the fusion proteins of the present invention. Under the invention, the LKT 111 leukotoxin peptide is not necessarily physically derived from the sequence present in plasmid pCB111. Rather, it may be generated in any manner, including for example, by chemical synthesis or recombinant production. In addition, the amino acid sequence of the protein need only be substantially homologous to the depicted sequence. Thus, sequence variations may be present so long as the protein functions to enhance the immunogenicity of antigen with which it is associated and lacks leukotoxicity.

A leukotoxin-GnRH polypeptide chimera displays "increased immunogenicity" when it possesses a greater capacity to elicit an immune response than the corresponding GnRH multimer alone. Such increased immunogenicity can be determined by administering the particular leukotoxin-GnRH polypeptide and GnRH multimer controls to animals and comparing antibody titres against the two using standard assays such as radioimmunoassays and ELISAs, well known in the art.

"Recombinant" proteins or polypeptides refer to polypeptides produced by recombinant DNA techniques; i.e., produced from cells transformed by an exogenous DNA construct encoding the desired polypeptide. "Synthetic" proteins or polypeptides are those prepared by chemical synthesis.

A DNA "coding sequence" or a "nucleotide sequence encoding" a particular protein, is a DNA sequence which is transcribed and translated into a polypeptide *in vivo* or *in vitro* when placed under the control of appropriate regulatory sequences. The boundaries of the coding sequence are determined by a start codon at the 5' (amino) terminus and a translation stop codon at the 3' (carboxy) terminus. A coding

sequence can include, but is not limited to, procaryotic sequences, cDNA from eucaryotic mRNA, genomic DNA sequences from eucaryotic (e.g., mammalian) DNA, and even synthetic DNA sequences. A transcription termination
5 sequence will usually be located 3' to the coding sequence.

DNA "control sequences" refer collectively to promoter sequences, ribosome binding sites, polyadenylation signals, transcription termination
10 sequences, upstream regulatory domains, enhancers, and the like, which collectively provide for the transcription and translation of a coding sequence in a host cell.

A coding sequence is "operably linked to" another coding sequence when RNA polymerase will transcribe the two coding sequences into mRNA, which is then translated into a chimeric polypeptide encoded by the two coding sequences. The coding sequences need not be contiguous to one another so long as the transcribed
15 sequence is ultimately processed to produce the desired chimeric protein. A control sequence is "operably linked to" a coding sequence when it controls the transcription of the coding sequence.

A control sequence "directs the transcription" of a coding sequence in a cell when RNA polymerase will bind the promoter sequence and transcribe the coding sequence into mRNA, which is then translated into the polypeptide encoded by the coding sequence.
25

A "host cell" is a cell which has been transformed, or is capable of transformation, by an exogenous DNA sequence.
30

A cell has been "transformed" by exogenous DNA when such exogenous DNA has been introduced inside the cell membrane. Exogenous DNA may or may not be
35 integrated (covalently linked) to chromosomal DNA making

up the genome of the cell. In procaryotes and yeasts, for example, the exogenous DNA may be maintained on an episomal element, such as a plasmid. With respect to eucaryotic cells, a stably transformed cell is one in which the exogenous DNA has become integrated into the chromosome so that it is inherited by daughter cells through chromosome replication. This stability is demonstrated by the ability of the eucaryotic cell to establish cell lines or clones comprised of a population of daughter cell containing the exogenous DNA.

Two DNA or polypeptide sequences are "substantially homologous" when at least about 80% (preferably at least about 90%, and most preferably at least about 95%) of the nucleotides or amino acids match over a defined length of the molecule. DNA sequences that are substantially homologous can be identified in a Southern hybridization experiment under, for example, stringent conditions, as defined for that particular system. Defining appropriate hybridization conditions is within the skill of the art. See, e.g., Sambrook et al., supra; DNA Cloning, vols I & II, supra; Nucleic Acid Hybridization, supra.

A "heterologous" region of a DNA construct is an identifiable segment of DNA within or attached to another DNA molecule that is not found in association with the other molecule in nature. Thus, when the heterologous region encodes a bacterial gene, the gene will usually be flanked by DNA that does not flank the bacterial gene in the genome of the source bacteria. Another example of the heterologous coding sequence is a construct where the coding sequence itself is not found in nature (e.g., synthetic sequences having codons different from the native gene). Allelic variation or naturally occurring mutational events do not give rise to a heterologous region of DNA, as used herein.

By "vertebrate subject" is meant any member of the subphylum chordata, including, without limitation, mammals such as rodents, cattle, pigs, sheep, goats, horses and man; domestic animals such as dogs and cats; birds, including domestic, wild and game birds such as cocks and hens including chickens, turkeys and other gallinaceous birds. The term does not denote a particular age. Thus, both adult and newborn animals are intended to be covered.

B. General Methods

Central to the instant invention is the discovery that leukotoxin polypeptides, when coupled to selected GnRH polypeptide repeats (or multimers), are able to confer superior immunogenicity to the associated GnRH moieties. In this regard, leukotoxin polypeptides act as carrier proteins which present selected GnRH multimers to a subject's immune system in a highly immunogenic form. Thus, chimeric proteins constructed under the invention may be formulated into vaccine compositions which provide enhanced immunogenicity to GnRH polypeptides presented therewith. Fusion of the leukotoxin gene to selected GnRH polypeptides also facilitates purification of the chimeric protein from cells expressing the same.

Accordingly, exemplified herein are leukotoxin chimeras which include leukotoxin fused to more than one GnRH peptide sequence. Particularly contemplated embodiments of the present invention include chimeras comprising a leukotoxin polypeptide fused to a GnRH multimer, wherein said multimer consists essentially of at least one repeating GnRH decapeptide sequence, or at least one repeating unit of a sequence corresponding to at least one epitope of a selected GnRH molecule. Further, the selected GnRH peptide sequences may all be

the same, or may correspond to different derivatives, analogues, variants or epitopes of GnRH so long as they retain the ability to elicit an immune response. A representative nucleotide sequence of a GnRH decapeptide is depicted in Figure 1A. The subject GnRH sequence is modified by the substitution of a glutamine residue at the N-terminal in place of pyroglutamic acid which is found in the native sequence. This particular substitution renders a molecule that retains the native glutamic acid structure but also preserves the uncharged structure of pyroglutamate. Accordingly, the resulting peptide does not require cyclization of the glutamic acid residue and may be produced in the absence of conditions necessary to effect cyclization.

Because the GnRH sequence is relatively short, it can easily be generated using synthetic techniques, as described in detail below. Under the invention, a leukotoxin polypeptide sequence is used to confer immunogenicity upon associated GnRH polypeptides (as a carrier protein) in order to help elicit an adequate immune response toward endogenous GnRH in a vertebrate subject. In this manner, immunization with GnRH can regulate fertility in a vaccinated subject by disruption of estrous cycles or spermatogenesis. A detailed discussion of GnRH can be found in U.S. Patent No. 4,975,420.

Further, it is particularly contemplated herein to provide a reliable and effective alternative to invasive sterilization procedures currently practiced in domestic and farm animal husbandry, such as surgical castration, surgical ovariectomy and the like. Immunosuppression of reproductive activity in vertebrate subjects using leukotoxin-GnRH chimeras constructed according to the present invention provides an effective alternative in that the constructs effect uniform

inactivation of reproductive activity in immunized animals. In this regard, a suitable sterilization vaccine product must serve to uniformly inactivate reproductive capabilities in individual animals in response to a minimum of vaccinations in order to provide a successful alternative to surgical procedures. This feature is particularly important for immunosterilization of herd animals, and particularly where it is desired to immunocastrate male piglets to prevent "boar taint" which is produced by the synthesis of sex steroids in normally functioning testicles of male piglets. See e.g. Meloen et al., Vaccine (1994) 12(8):741-746. Prior attempts at developing such a product have not produced uniform results due to the insufficient immunogenicity of GnRH peptides and/or related carrier systems, and the resultant inability of various prior GnRH-based vaccines to induce sufficient immune responses toward endogenous GnRH.

Accordingly, leukotoxin-GnRH polypeptide chimeras contemplated herein comprise a GnRH portion that corresponds to more than one selected GnRH polypeptide sequence in order to render a more immunogenic GnRH peptide antigen. This feature is based on the recognition that endogenous proteins in general may be rendered effective autoantigens by multimerization of their epitopes as described in detail above. More particularly, the GnRH portion of the novel chimeras contemplated herein may comprise either multiple or tandem repeats of selected GnRH sequences, multiple or tandem repeats of selected GnRH epitopes, or any conceivable combination thereof. In this regard, GnRH epitopes may be identified using techniques as described in detail above, or fragments of GnRH proteins may be tested for immunogenicity and active fragments used in compositions in lieu of the entire polypeptide. The

sequence of a particularly contemplated GnRH portion under the present invention is depicted in Figure 1B wherein four GnRH sequences, indicated at (1), (2), (3) and (4) respectively, are separated by triplet amino acid spacer sequences comprising various combinations of serine and glycine residues. In the subject oligomer, every other GnRH sequence (those indicated at (2) and (4), respectively) contains a non-conservative amino acid substitution at the second position of the GnRH decapeptide comprising an Asp residue in place of the His residue found in the native GnRH sequence. The alternating GnRH multimeric sequence thus produced renders a highly immunogenic GnRH antigen peptide for use in the fusion proteins of the invention. Other GnRH analogues corresponding to any single or multiple amino acid additions, substitutions and/or deletions are also particularly contemplated herein for use in either repetitive or alternating multimeric sequences.

Furthermore, the particular GnRH portion depicted in Figure 1B contains spacer sequences between the GnRH moieties. The present invention particularly contemplates the strategic use of various spacer sequences between selected GnRH polypeptides in order to confer increased immunogenicity on the subject constructs. Accordingly, under the invention, a selected spacer sequence may encode a wide variety of moieties of one or more amino acids in length. Selected spacer groups may preferably provide enzyme cleavage sites so that the expressed chimera can be processed by proteolytic enzymes in vivo (by APC's or the like) to yield a number of peptides --each of which contain at least one T-cell epitope derived from the carrier portion (leukotoxin portion)-- and which are preferably fused to a substantially complete GnRH polypeptide sequence. Further, spacer groups may be constructed so that the

junction region between selected GnRH moieties comprises a clearly foreign sequence to the immunized subject, thereby conferring enhanced immunogenicity upon the associated GnRH peptides. Additionally, spacer sequences
5 may be constructed so as to provide T-cell antigenicity, such as sequences which encode amphipathic and/or α -helical peptide sequences which are generally regarded in the art as providing immunogenic helper T-cell epitopes. In this regard, the choice of particular T-cell epitopes
10 to be provided by such spacer sequences may vary depending on the particular vertebrate species to be vaccinated. Although, particular GnRH portions are exemplified which include spacer sequences, it is also contemplated herein to provide a GnRH multimer comprising
15 directly adjacent GnRH sequences (without intervening spacer sequences).

The leukotoxin-GnRH polypeptide complex can be conveniently produced recombinantly as a chimeric protein. The GnRH portion of the chimera can be fused
20 either 5' or 3' to the leukotoxin portion of the molecule, or the GnRH portion may be located at sites internal to the leukotoxin molecule. The nucleotide sequence coding for full-length *P. haemolytica* A1 leukotoxin has been determined. See, e.g., Lo, *Infect. Immun.* (1987) 55:1987-1996; U.S. Patent No. 5,055,400.
25 Additionally, several variant leukotoxin gene sequences are disclosed herein.

Similarly, the coding sequences for porcine, bovine and ovine GnRH have been determined, (Murad et al., *Hormones and Hormone Antagonists*, in The Pharmacological Basis of Therapeutics, Sixth Edition
30 (1980)), and the cDNA for human GnRH has been cloned so that its sequence has been well established (Seeburg et al., *Nature* (1984) 311:666-668). Additional GnRH
35 polypeptides of known sequences have been disclosed, such

as the GnRH molecule occurring in salmon and chickens (International Publication No. WO 86/07383, published 18 December 1986). In this regard, it is noted that GnRH is highly conserved in vertebrates, particularly in mammals; and further that porcine, bovine, ovine and human GnRH sequences are identical to one another. The desired leukotoxin and GnRH genes can be cloned, isolated and ligated together using recombinant techniques generally known in the art. See, e.g., Sambrook et al., supra.

Alternatively, DNA sequences encoding the chimeric proteins can be prepared synthetically rather than cloned. The DNA sequence can be designed with the appropriate codons for the particular amino acid sequence. In general, one will select preferred codons for the intended host if the sequence will be used for expression. The complete sequence is assembled from overlapping oligonucleotides prepared by standard methods and assembled into a complete coding sequence. See, e.g., Edge, Nature (1981) 292:756; Nambair et al. Science (1984) 223:1299; Jay et al. J. Biol. Chem. (1984) 259:6311.

Once coding sequences for the chimeric proteins have been prepared or isolated, they can be cloned into any suitable vector or replicon. Numerous cloning vectors are known to those of skill in the art, and the selection of an appropriate cloning vector is a matter of choice. Examples of recombinant DNA vectors for cloning and host cells which they can transform include the bacteriophage lambda (E. coli), pBR322 (E. coli), pACYC177 (E. coli), pKT230 (gram-negative bacteria), pGV1106 (gram-negative bacteria), pLAFR1 (gram-negative bacteria), pME290 (non-E. coli gram-negative bacteria), pHV14 (E. coli and Bacillus subtilis), pBD9 (Bacillus), pIJ61 (Streptomyces), pUC6 (Streptomyces), YIp5 (Saccharomyces), YCp19 (Saccharomyces) and bovine

papilloma virus (mammalian cells). See, generally, DNA Cloning: Vols. I & II, supra; T. Maniatis et al., supra; B. Perbal, supra.

5 The fusion gene can be placed under the control of a promoter, ribosome binding site (for bacterial expression) and, optionally, an operator (collectively referred to herein as "control" elements), so that the DNA sequence encoding the chimeric protein is transcribed into RNA in the host cell transformed by a vector
10 containing this expression construction. The coding sequence may or may not contain a signal peptide or leader sequence. The chimeric proteins of the present invention can be expressed using, for example, native *P. haemolytica* promoter, the *E. coli* tac promoter or the
15 protein A gene (*spa*) promoter and signal sequence. Leader sequences can be removed by the bacterial host in post-translational processing. See, e.g., U.S. Patent Nos. 4,431,739; 4,425,437; 4,338,397.

In addition to control sequences, it may be
20 desirable to add regulatory sequences which allow for regulation of the expression of the protein sequences relative to the growth of the host cell. Regulatory sequences are known to those of skill in the art, and examples include those which cause the expression of a
25 gene to be turned on or off in response to a chemical or physical stimulus, including the presence of a regulatory compound. Other types of regulatory elements may also be present in the vector, for example, enhancer sequences.

An expression vector is constructed so that the
30 particular fusion coding sequence is located in the vector with the appropriate regulatory sequences, the positioning and orientation of the coding sequence with respect to the control sequences being such that the coding sequence is transcribed under the "control" of the
35 control sequences (i.e., RNA polymerase which binds to

the DNA molecule at the control sequences transcribes the coding sequence). Modification of the sequences encoding the particular chimeric protein of interest may be desirable to achieve this end. For example, in some cases it may be necessary to modify the sequence so that it may be attached to the control sequences with the appropriate orientation; i.e., to maintain the reading frame. The control sequences and other regulatory sequences may be ligated to the coding sequence prior to insertion into a vector, such as the cloning vectors described above. Alternatively, the coding sequence can be cloned directly into an expression vector which already contains the control sequences and an appropriate restriction site.

In some cases, it may be desirable to add sequences which cause the secretion of the polypeptide from the host organism, with subsequent cleavage of the secretory signal. It may also be desirable to produce mutants or analogues of the chimeric proteins of interest. Mutants or analogues may be prepared by the deletion of a portion of the sequence encoding the protein, by insertion of a sequence, and/or by substitution of one or more nucleotides within the sequence. Techniques for modifying nucleotide sequences, such as site-directed mutagenesis, are well known to those skilled in the art. See, e.g., T. Maniatis et al., supra; DNA Cloning, Vols. I and II, supra; Nucleic Acid Hybridization, supra.

A number of procaryotic expression vectors are known in the art. See, e.g., U.S. Patent Nos. 4,440,859; 4,436,815; 4,431,740; 4,431,739; 4,428,941; 4,425,437; 4,418,149; 4,411,994; 4,366,246; 4,342,832; see also U.K. Patent Applications GB 2,121,054; GB 2,008,123; GB 2,007,675; and European Patent Application 103,395. Yeast expression vectors are also known in the art. See,

e.g., U.S. Patent Nos. 4,446,235; 4,443,539; 4,430,428; see also European Patent Applications 103,409; 100,561; 96,491.

5 Depending on the expression system and host selected, the proteins of the present invention are produced by growing host cells transformed by an expression vector described above under conditions whereby the protein of interest is expressed. The chimeric protein is then isolated from the host cells and purified. If
10 the expression system secretes the protein into growth media, the protein can be purified directly from the media. If the protein is not secreted, it is isolated from cell lysates. The selection of the appropriate growth conditions and recovery methods are within the
15 skill of the art.

The chimeric proteins of the present invention may also be produced by chemical synthesis such as solid phase peptide synthesis, based on the determined amino acid sequences. Such methods are known to those skilled
20 in the art. See, e.g., J. M. Stewart and J. D. Young, *Solid Phase Peptide Synthesis*, 2nd Ed., Pierce Chemical Co., Rockford, IL (1984) and G. Barany and R. B. Merrifield, *The Peptides: Analysis, Synthesis, Biology*, editors E. Gross and J. Meienhofer, Vol. 2, Academic
25 Press, New York, (1980), pp. 3-254, for solid phase peptide synthesis techniques; and M. Bodansky, *Principles of Peptide Synthesis*, Springer-Verlag, Berlin (1984) and E. Gross and J. Meienhofer, Eds., *The Peptides: Analysis, Synthesis, Biology*, supra, Vol. 1, for classical solution
30 synthesis.

Subjects can be immunized with chimeric proteins constructed according to the present invention by administration of vaccine compositions which include said proteins. Prior to immunization, it may be
35 desirable to further increase the immunogenicity of the

particular chimeric protein. This can be accomplished in any one of several ways known to those of skill in the art. For example, the leukotoxin-GnRH polypeptide fusion protein may be administered linked to a secondary carrier. For example, a fragment may be conjugated with a macromolecular carrier. Suitable carriers are typically large, slowly metabolized macromolecule such as: proteins; polysaccharides, such as sepharose, agarose, cellulose, cellulose beads and the like; polymeric amino acids such as polyglutamic acid, polylysine, and the like; amino acid copolymers; and inactive virus particles. Especially useful protein substrates are serum albumins, keyhole limpet hemocyanin, immunoglobulin molecules, thyroglobulin, ovalbumin, and other proteins well known to those skilled in the art.

The protein substrates may be used in their native form or their functional group content may be modified by, for example, succinylation of lysine residues or reaction with Cys-thiolactone. A sulfhydryl group may also be incorporated into the carrier (or selected GnRH polypeptides) by, for example, reaction of amino functions with 2-iminothiolane or the N-hydroxysuccinimide ester of 3-(4-dithiopyridyl) propionate. Suitable carriers may also be modified to incorporate spacer arms (such as hexamethylene diamine or other bifunctional molecules of similar size) for attachment of peptides.

Other suitable carriers for the chimeric proteins of the present invention include VP6 polypeptides of rotaviruses, or functional fragments thereof, as disclosed in U.S. Patent No. 5,071,651. Also useful is a fusion product of a viral protein and a leukotoxin-GnRH immunogen, where that fusion product is made by methods disclosed in U.S. Patent No. 4,722,840. Still other suitable carriers include cells, such as

lymphocytes, since presentation in this form mimics the natural mode of presentation in the subject, which gives rise to the immunized state. Alternatively, the fusion proteins of the present invention may be coupled to erythrocytes, preferably the subject's own erythrocytes. Methods of coupling peptides to proteins or cells are known to those of skill in the art.

The novel chimeric proteins of the instant invention can also be administered via a carrier virus which expresses the same. Carrier viruses which will find use with the instant invention include but are not limited to the vaccinia and other pox viruses, adenovirus, and herpes virus. By way of example, vaccinia virus recombinants expressing the novel chimeric proteins can be constructed as follows. The DNA encoding the particular leukotoxin-GnRH chimeric protein is first inserted into an appropriate vector so that it is adjacent to a vaccinia promoter and flanking vaccinia DNA sequences, such as the sequence encoding thymidine kinase (TK). This vector is then used to transfect cells which are simultaneously infected with vaccinia. Homologous recombination serves to insert the vaccinia promoter plus the gene encoding the instant chimeric protein into the viral genome. The resulting TK-recombinant can be selected by culturing the cells in the presence of 5-bromodeoxyuridine and picking viral plaques resistant thereto.

It is also possible to immunize a subject with chimeric proteins produced according to the present invention, either administered alone, or mixed with a pharmaceutically acceptable vehicle or excipient. Typically, vaccines are prepared as injectables, either as liquid solutions or suspensions; solid forms suitable for solution in, or suspension in, liquid vehicles prior to injection may also be prepared. The preparation may

also be emulsified or the active ingredient encapsulated in liposome vehicles. The active immunogenic ingredient is often mixed with vehicles containing excipients which are pharmaceutically acceptable and compatible with the active ingredient. Suitable vehicles are, for example, water, saline, dextrose, glycerol, ethanol, or the like, and combinations thereof. In addition, if desired, the vehicle may contain minor amounts of auxiliary substances such as wetting or emulsifying agents, pH buffering agents, or adjuvants which enhance the effectiveness of the vaccine. Adjuvants may include for example, muramyl dipeptides, avridine, aluminum hydroxide, oils, saponins and other substances known in the art. Actual methods of preparing such dosage forms are known, or will be apparent, to those skilled in the art. See, e.g., Remington's Pharmaceutical Sciences, Mack Publishing Company, Easton, Pennsylvania, 18th edition, 1990. The composition or formulation to be administered will, in any event, contain a quantity of the protein adequate to achieve the desired immunized state in the subject being treated.

Additional vaccine formulations which are suitable for other modes of administration include suppositories and, in some cases, aerosol, intranasal, oral formulations, and sustained release formulations. For suppositories, the vehicle composition will include traditional binders and carriers, such as, polyalkaline glycols, or triglycerides. Such suppositories may be formed from mixtures containing the active ingredient in the range of about 0.5% to about 10% (w/w), preferably about 1% to about 2%. Oral vehicles include such normally employed excipients as, for example, pharmaceutical grades of mannitol, lactose, starch, magnesium, stearate, sodium saccharin cellulose, magnesium carbonate, and the like. These oral vaccine compositions may be taken in the form of solutions,

suspensions, tablets, pills, capsules, sustained release formulations, or powders, and contain from about 1% to about 30% of the active ingredient, preferably about 2% to about 20%.

5 Intranasal formulations will usually include vehicles that neither cause irritation to the nasal mucosa nor significantly disturb ciliary function. Diluents such as water, aqueous saline or other known substances can be employed with the subject invention.
10 The nasal formulations may also contain preservatives such as, but not limited to, chlorobutanol and benzalkonium chloride. A surfactant may be present to enhance absorption of the subject proteins by the nasal mucosa.

15 Controlled or sustained release formulations are made by incorporating the chimeric proteins into carriers or vehicles such as liposomes, nonresorbable impermeable polymers such as ethylenevinyl acetate copolymers and Hytrel® copolymers, swellable polymers
20 such as hydrogels, or resorbable polymers such as collagen and certain polyacids or polyesters such as those used to make resorbable sutures. The chimeric proteins can also be presented using implanted mini-pumps, well known in the art.

25 Furthermore, the chimeric proteins (or complexes thereof) may be formulated into vaccine compositions in either neutral or salt forms. Pharmaceutically acceptable salts include the acid
30 addition salts (formed with the free amino groups of the active polypeptides) and which are formed with inorganic acids such as, for example, hydrochloric or phosphoric acids, or such organic acids as acetic, oxalic, tartaric, mandelic, and the like. Salts formed from free carboxyl
35 groups may also be derived from inorganic bases such as, for example, sodium, potassium, ammonium, calcium, or

ferric hydroxides, and such organic bases as isopropylamine, trimethylamine, 2-ethylamino ethanol, histidine, procaine, and the like.

To immunize a subject, a selected GnRH-leukotoxin chimera is administered parenterally, usually by intramuscular injection in an appropriate vehicle. Other modes of administration, however, such as subcutaneous, intravenous injection and intranasal delivery, are also acceptable. Injectable vaccine formulations will contain an effective amount of the active ingredient in a vehicle, the exact amount being readily determined by one skilled in the art. The active ingredient may typically range from about 1% to about 95% (w/w) of the composition, or even higher or lower if appropriate. The quantity to be administered depends on the animal to be treated, the capacity of the animal's immune system to synthesize antibodies, and the degree of protection desired.

With the present vaccine formulations, approximately 1 μ g to 1 mg, more generally 5 μ g to 200 μ g of GnRH polypeptide per ml of injected solution, should be adequate to raise an immunological response when administered. In this regard, the ratio of GnRH to leukotoxin in the Leukotoxin-GnRH antigens of the subject vaccine formulations will vary based on the particular leukotoxin and GnRH polypeptide moieties selected to construct those molecules. More particularly, in the leukotoxin-GnRH polypeptides used in producing the vaccine formulations under the invention, there will be about 1 to 25% GnRH, preferably about 3 to 20% and most preferably about 7 to 17% GnRH polypeptide per fusion molecule. Increases in the percentage of GnRH present in the LKT-GnRH antigens reduces the amount of total antigen which must be administered to a subject in order to elicit an effective B-cell response to GnRH. Effective

dosages can be readily established by one of ordinary skill in the art through routine trials establishing dose response curves. The subject is immunized by administration of the particular leukotoxin-GnRH polypeptide in at least one dose, and preferably two doses. Moreover, the animal may be administered as many doses as is required to maintain a state of immunity.

Below are examples of specific embodiments for carrying out the present invention. The examples are offered for illustrative purposes only, and are not intended to limit the scope of the present invention in any way.

C. ExperimentalMaterials and Methods

Enzymes were purchased from commercial sources, and used according to the manufacturers' directions. Radionucleotides and nitrocellulose filters were also purchased from commercial sources.

In the cloning of DNA fragments, except where noted, all DNA manipulations were done according to standard procedures. See Sambrook et al., supra. Restriction enzymes, T₄ DNA ligase, *E. coli*, DNA polymerase I, Klenow fragment, and other biological reagents were purchased from commercial suppliers and used according to the manufacturers' directions. Double-stranded DNA fragments were separated on agarose gels.

cDNA and genomic libraries were prepared by standard techniques in pUC13 and the bacteriophage lambda gt11, respectively. See DNA CLONING: Vols I and II, supra.

P. haemolytica biotype A, serotype 1 ("A1") strain B122 was isolated from the lung of a calf which died of pneumonic pasteurellosis and was stored at -70°C in defibrinated blood. Routine propagation was carried out on blood agar plates or in brain heart infusion broth (Difco Laboratories, Detroit, MI) supplemented with 5% (v/v) horse serum (Gibco Canada Ltd., Burlington, Canada). All cultures were incubated at 37°C.

Example 1

30 Isolation of *P. haemolytica* Leukotoxin Gene

To isolate the leukotoxin gene, gene libraries of *P. haemolytica* A1 (strain B122) were constructed using standard techniques. See, Lo et al., *Infect. Immun.*, supra; DNA CLONING: Vols. I and II, supra; and Sambrook et al., supra. A genomic library was constructed in the

plasmid vector pUC13 and a DNA library constructed in the bacteriophage lambda gt11. The resulting clones were used to transform *E. coli* and individual colonies were pooled and screened for reaction with serum from a calf which had survived a *P. haemolytica* infection and that had been boosted with a concentrated culture supernatant of *P. haemolytica* to increase anti-leukotoxin antibody levels. Positive colonies were screened for their ability to produce leukotoxin by incubating cell lysates with bovine neutrophils and subsequently measuring release of lactate dehydrogenase from the latter.

Several positive colonies were identified and these recombinants were analyzed by restriction endonuclease mapping. One clone appeared to be identical to a leukotoxin gene cloned previously. See, Lo et al., *Infect. Immun.*, supra. To confirm this, smaller fragments were re-cloned and the restriction maps compared. It was determined that approximately 4 kilobase pairs of DNA had been cloned. Progressively larger clones were isolated by carrying out a chromosome walk (5' to 3' direction) in order to isolate full-length recombinants which were approximately 8 kb in length. The final construct was termed pAA114. This construct contained the entire leukotoxin gene sequence.

lktA, a *MaeI* restriction endonuclease fragment from pAA114 which contained the entire leukotoxin gene, was treated with the Klenow fragment of DNA polymerase I plus nucleotide triphosphates and ligated into the *SmaI* site of the cloning vector pUC13. This plasmid was named pAA179. From this, two expression constructs were made in the *ptac*-based vector pGH432:*lacI* digested with *SmaI*. One, pAA342, consisted of the 5'-*AhaIII* fragment of the *lktA* gene while the other, pAA345, contained the entire *MaeI* fragment described above. The clone pAA342 expressed a truncated leukotoxin peptide at high levels

while pAA345 expressed full length leukotoxin at very low levels. Therefore, the 3' end of the lktA gene (StyI BamHI fragment from pAA345) was ligated to StyI BamHI-digested pAA342, yielding the plasmid pAA352. The structure of pAA352 is shown in Figure 2 and the nucleotide sequence and predicted amino acid sequence of *P. haemolytica* leukotoxin produced from the pAA352 construct (hereinafter LKT 352) is shown in Figure 3.

10

Example 2

Construction of LKT-GnRH Fusions

Representative LKT-GnRH fusions were constructed as follows. Oligonucleotides containing sequences corresponding to single copy GnRH and GnRH as four multiple repeats were constructed on a Pharmacia Gene Assembler using standard phosphoramidite chemistry. The sequences of these oligonucleotides are shown in Figures 1A and 1B. The subject oligonucleotides were annealed and ligated into the vector pAA352 (ATCC No. 68283, and described above), which had been digested with the restriction endonuclease BamHI. This vector contains the *P. haemolytica* leukotoxin gene. The ligated DNA was used to transform *E. coli* strain MH3000. Transformants containing the oligonucleotide inserts were identified by restriction endonuclease mapping.

An eight copy GnRH tandem repeat sequence was prepared by annealing the four copy GnRH oligonucleotides and ligating them into a vector which had been digested with the restriction endonuclease BamHI. The oligomers were designed to disable the upstream BamHI site when inserted and to ensure that the insertion of additional copies of the oligomer would be oriented in the proper reading frame. The sequence of the subject oligonucleotide is shown in Figure 1B. Plasmid DNA from the *E. coli* MH3000 strain was then isolated and used to

transform the strain JM105. The recombinant plasmids were designated pCB113 (LKT 352:4 copy GnRH, ATCC Accession No. 69749) and pCB112 (LKT 352:8 copy GnRH). Recombinant plasmid pCB113 is shown in Figure 4, plasmid pCB112 is identical to pCB113 except that the multiple copy GnRH sequence (corresponding to the oligomer of Figure 1B) was inserted twice as described above. The nucleotide sequence of the recombinant LKT-GnRH fusion of pCB113 is shown in Figure 5. The nucleotide sequence of the recombinant LKT-GnRH fusion pCB112 is identical except that the multiple copy GnRH sequence was inserted twice.

Example 3

Construction of Shortened LKT Carrier Peptide

A shortened version of the recombinant leukotoxin peptide was constructed from the recombinant gene present on the plasmid pAA352 (as described above). The shortened LKT gene was produced by deleting an internal DNA fragment of approximately 1300 bp in length from the recombinant LKT gene as follows.

The plasmid pCB113, (ATCC Accession No. 69749) which includes the LKT 352 polypeptide fused to four copies of the GnRH polypeptide, was digested with the restriction enzyme *BstB1* (New England Biolabs). The resultant linearized plasmid was then digested with mung-bean nuclease (Pharmacia) to remove the single stranded protruding termini produced by the *BstB1* digestion. The blunted DNA was then digested with the restriction enzyme *NaeI* (New England Biolabs), and the digested DNA was loaded onto a 1% agarose gel where the DNA fragments were separated by electrophoresis. A large DNA fragment of approximately 6190 bp was isolated and purified from the agarose gel using a Gene Clean kit (Bio 101), and the purified fragment was allowed to ligate to itself using

bacteriophage T4 DNA ligase (Pharmacia). The resulting ligation mix was used to transform competent *E. coli* JM105 cells, and positive clones were identified by their ability to produce an aggregate protein having a molecular weight of approximately 57 KDa. The recombinant plasmid thus formed was designated pCB111, (ATCC Accession No. 69748), and produces a shortened leukotoxin polypeptide (hereinafter referred to as LKT 111) fused to four copies of GnRH polypeptide. The structure of pCB111 is shown in Figure 6. Plasmid pCB114 is identical to pCB111 except that the multiple copy GnRH sequence (corresponding to the oligomer of Figure 1B) was inserted twice. The nucleotide sequence of the recombinant LKT-GnRH fusion of pCB111 is shown in Figure 7, the nucleotide sequence of the recombinant LKT-GnRH fusion of pCB114 is identical except that the multiple copy GnRH sequence was inserted twice.

The nucleotide sequence of the ligation fusion point of the subject clones has been confirmed by sequencing with a bacteriophage T7 polymerase sequencing kit (Pharmacia). The nucleotide sequences of these fusion points are shown in Figure 8.

Example 4

Purification of LKT-antigen Fusions

The recombinant LKT-GnRH fusions from Examples 2 and 3 were purified using the following procedure. For each fusion, five to ten colonies of the transformed *E. coli* strains were inoculated into 10 ml of TB broth supplemented with 100 micrograms/ml of ampicillin and incubated at 37°C for 6 hours on a G10 shaker, 220 rpm. Four ml of this culture was diluted into each of two baffled Fernbach flasks containing 400 ml of TB broth + ampicillin and incubated overnight as described above. Cells were harvested by centrifugation for 10 minutes at

4,000 rpm in polypropylene bottles, 500 ml volume, using a Sorvall GS3 rotor. The pellet was resuspended in an equal volume of TB broth containing ampicillin which had been prewarmed to 37°C (i.e., 2 x 400 ml), and the cells were incubated for 2 hours as described above.

3.2 ml of isopropyl-B,D-thiogalactopyranoside (IPTG, Gibco/BRL), 500 mM in water (final concentration = 4 mM), was added to each culture in order to induce synthesis of the recombinant fusion proteins. Cultures were incubated for two hours. Cells were harvested by centrifugation as described above, resuspended in 30 ml of 50 mM Tris-hydrochloride, 25% (w/v) sucrose, pH 8.0, and frozen at -70°C. The frozen cells were thawed at room temperature after 60 minutes at -70°C, and 5 ml of lysozyme (Sigma, 20 mg/ml in 250 mM Tris-HCl, pH 8.0) was added. The mixture was vortexed at high speed for 10 seconds and then placed on ice for 15 minutes. The cells were then added to 500 ml of lysis buffer in a 1000 ml beaker and mixed by stirring with a 2 ml pipette. The beaker containing the lysed cell suspension was placed on ice and sonicated for a total of 2.5 minutes (5-30 second bursts with 1 minute cooling between each) with a Braun sonicator, large probe, set at 100 watts power. Equal volumes of the solution were placed in Teflon SS34 centrifuge tubes and centrifuged for 20 minutes at 10,000 rpm in a Sorvall SS34 rotor. The pellets were resuspended in a total of 100 ml of sterile double distilled water by vortexing at high speed, and the centrifugation step repeated. Supernatants were discarded and the pellets combined in 20 ml of 10 mM Tris-HCl, 150 mM NaCl, pH 8.0 (Tris-buffered saline) and the suspension frozen overnight at -20°C.

The recombinant suspension was thawed at room temperature and added to 100 ml of 8 M Guanidine HCl (Sigma) in Tris-buffered saline and mixed vigorously. A

magnetic stir bar was placed in the bottle and the solubilized sample was mixed at room temperature for 30 minutes. The solution was transferred to a 2000 ml Erlenmyer flask and 1200 ml of Tris-buffered saline was added quickly. This mixture was stirred at room temperature for an additional 2 hours. 500 ml aliquots were placed in dialysis bags (Spectrum, 63.7 mm diameter, 6,000-8,000 MW cutoff, #132670, from Fisher scientific) and these were placed in 4,000 ml beakers containing 3,500 ml of Tris-buffered saline + 0.5 M Guanidine HCl. The beakers were placed in a 4°C room on a magnetic stirrer overnight after which dialysis buffer was replaced with Tris-buffered saline + 0.1 M Guanidine HCl and dialysis continued for 12 hours. The buffer was then replaced with Tris-buffered saline + 0.05 M Guanidine HCl and dialysis continued overnight. The buffer was replaced with Tris-buffered saline (no guanidine), and dialysis continued for 12 hours. This was repeated three more times. The final solution was poured into a 2000 ml plastic roller bottle (Corning) and 13 ml of 100 mM PMSF (in ethanol) was added to inhibit protease activity. The solution was stored at -20°C in 100 ml aliquots.

To confirm that the fusion proteins had been isolated, aliquots of each preparation were diluted 20-fold in double distilled water, mixed with an equal volume of SDS-PAGE sample buffer, placed in a boiling water bath for five minutes and run through 12% polyacrylamide gels. Recombinant leukotoxin controls were also run.

All fusion proteins were expressed at high levels as inclusion bodies. The predicted molecular weights based on the DNA sequences of the fusion proteins were 104,869 (LKT 352::4 copy GnRH, from pCB113); 110,392 (LKT 352::8 copy GnRH, from pCB112); 57,542 (LKT 111::4 copy GnRH, from pCB111); and 63,241 (LKT 111::8 copy GnRH

from pCB114). The predicted molecular weight of the recombinant LKT 352 molecule was 99,338, and the predicted molecular weight of the recombinant LKT 111 molecule was 51,843.

5

Example 5

In Vivo Immunologic Activity of LKT-GnRH Fusions

To test for the ability of LKT-GnRH fusions to induce an anti-GnRH immunological response *in vivo*, and to compare this response to other GnRH carrier conjugates, the following vaccination trial was performed. Three groups of 8 male pigs, approximately 8 weeks of age (35-50 kg) were used which were Specific Pathogen Free. The animals were maintained in a minimal disease facility and were vaccinated on days 0 and 21 of the trial with the following formulations:

Group 1 -- placebo which consisted of saline formulated in Emulsigen Plus adjuvant containing 15 mg of DDA (2 ml);

Group 2 -- LKT 352-GnRH (250 µg LKT, prepared as described in the previous examples) formulated in the same adjuvant (2 ml);

Group 3 -- VP6-GnRH, 0.5 µg VP6 and 5 µg GnRH, formulated in the same adjuvant (2 ml). The VP6 preparation was made as described in U.S. Patent No. 5,071,651, using the binding peptide described therein.

Blood samples were taken on days 0, 21 and 35, allowed to clot, centrifuged at 1500 g, and the serum removed. The serum antibody titres against GnRH were measured using the RIA procedure of Silversides et al., *J. Reprod. Immunol.* (1985) 7:171-184.

The results of this trial indicated that only those animals immunized with the LKT 352-GnRH formulation produced significant titres against GnRH (titres >1:70). Neither the placebo nor the VP6-GnRH groups produced

anti-GnRH titres. Previously, multiple vaccinations with doses of GnRH of more than 100 µg, conjugated to other carrier proteins, were required to induce anti-hormone titres. These results indicate that the LKT-GnRH carrier system provides a greatly improved immunogen over prior carrier systems.

Example 6

In Vivo Immunologic Effect of Multiple Tandem GnRH Repeats Ligated to LKT

To test for the ability of recombinant LKT-GnRH fusion proteins containing multiple GnRH polypeptide repeats to induce an anti-GnRH immunological response in vivo, the following vaccination trial was performed.

Cultures of *E. coli* containing plasmids pCB113 and pCB175 (having 4 and 8 copies of GnRH ligated to LKT 352, respectively) and a plasmid having 1 copy of GnRH ligated to LKT 352 were prepared as described above. Vaccines from each of the above cultures were formulated to contain the equivalent of 5 µg of GnRH in 0.2 ml of Emulsigen Plus. Three groups of 10 female mice were given two subcutaneous injections 23 days apart and blood samples were collected at days 23, 35 and 44 after the primary injection. Serum antibody titres against GnRH were measured at final dilutions of 1:100 and 1:1000 using a standard radioimmunoassay procedure. If less than 5% of the iodinated GnRH was bound, antibody was deemed to be undetectable. The antibody titres thus obtained are summarized in the Table 1.

The results of this study indicate that equal doses of GnRH presented as multiple tandem repeats (four or eight copy GnRH) gave a dramatic improvement in antibody production over single copy GnRH (as measured by binding to iodinated native GnRH). Further, the above results indicate that a fusion protein comprising a four

copy GnRH tandem repeat ligated to LKT 352 represents an optimal immunogenic GnRH antigen form, although immunogenicity may be influenced by dose or subject species.

Table 1

Example 7

In Vivo Immunologic Activity and Biologic Effect
of LKT 352::GnRH and LKT 111::GnRH Fusions

To test the ability of fusion proteins
5 comprising multiple tandem repeats of GnRH (ligated to
either LKT 352 or LKT 111) to elicit an anti-GnRH
immunological response in vivo and to manifest a biologic
effect in vivo, the following vaccination trial was
preformed. Cultures of *E. coli* containing plasmids
10 pCB113 and pCB111 (4 copy GnRH ligated to LKT 352 or LKT
111, respectively) were prepared as described above.
Vaccines from each of the above cultures were formulated
to contain the equivalent of 5 µg of GnRH in 0.2 ml of
VSA-3 adjuvant, (a modified Emulsigen Plus adjuvant),
15 with a control vaccine comprising 0.2 ml of the adjuvant
also being prepared. Three groups of 5 male Swiss mice
were given two subcutaneous injections 21 days apart,
with the initial injections (day 0) given at 5-6 weeks of
age. On day 49 the subjects were sacrificed.

20 Immunological activity of the subject GnRH-LKT
fusions was assayed by measuring anti-GnRH antibody
titres using a standard radioimmunoassay procedure at a
1:1000 serum dilution. Biological effect of the GnRH-LKT
fusions was quantified by standard radioimmunoassay of
25 serum testosterone levels with a sensitivity of 25 pg/ml,
and testicular tissue was weighed and histologically
examined. The results of this trial are summarized in
Table 2.

In the trial, all animal subjects injected with
30 GnRH:LKT antigens had readily detectable antibody levels;
however, the LKT 111::GnRH fusion (from plasmid pCB111)
showed superior immunogenicity as indicated by uniformity
of response and titre. Serum testosterone (produced by
the testicular Leydig cells) is secreted in a pulsatile
35 manner, and accordingly, low values and extreme

variability of serum levels are expected in normal animal subjects. Under the trial, the control group (receiving the 0.2 ml adjuvant vaccine injections) had normal serum testosterone levels, while both groups of treated
5 subjects had essentially undetectable serum testosterone.

Further under the trial, histological evaluation of testicular tissue revealed varying degrees of Leydig cell atrophy, reduced seminiferous tubule diameter and interruption of spermatogenesis in treated
10 subjects; however, testicular weight remained close to normal in treated animals—even in the presence of high anti-GnRH antibody titres—although there was clear evidence of testicular regression in 2 of 5 subjects receiving the LKT 111::4 copy GnRH fusions.

15 Accordingly, these results show that multiple copies of GnRH ligated to either LKT 352 or LKT 111 comprise potent immunogens; and further, it is indicated that vaccination with the subject fusion proteins triggers production of antibodies which are able to
20 neutralize endogenous GnRH in vivo, and that a concomitant in vivo biological effect is discernable in animal subjects receiving such vaccinations.

Table 2

Example 8

In Vivo Immunologic Activity of
LKT::GnRH Fusions in Porcine Subjects

To test the ability of fusion proteins

5 comprising multiple tandem repeats of GnRH (ligated to
either LKT 352 or LKT 111) to elicit anti-GnRH
immunological response in vivo in porcine subjects, the
following vaccination trial was preformed. Cultures of
10 *E. coli* containing plasmids pCB113, pCB111, pCB175 and
pCB114 (LKT 352::4 copy GnRH, LKT 111::4 copy GnRH, LKT
352::8 copy GnRH, and LKT 111::8 copy GnRH, respectively)
were prepared as described above. Vaccines from each of
the above cultures were formulated to contain the
equivalent of 50 µg GnRH and were administered in VSA-3
15 adjuvant in a 2.0 ml volume. Four groups of 5 male and 5
female weanling pigs, 35 days old (at day 0), were
injected at day 0 and reinjected at day 21 of the trial.
Blood samples were collected at days 0, 21 and 35, with
anti-GnRH antibody titres being measured at a final
20 dilution of 1:1000 using a standard radioimmunoassay
procedure. The assay results are summarized in Table 3.

Under the trial, anti-GnRH antibodies could not
be detected in any subjects prior to immunization, but
were readily detected in most subjects by day 35 (one
25 subject in treatment group 4 died due to an infection
unrelated to treatment). The results in this trial
indicate that fusion proteins comprising multiple GnRH
repeats ligated to either a LKT 352 or LKT 111 carrier
polypeptide form useful immunogens in porcine subjects.
30 Based on the predicted molecular weights of the
decapeptide GnRH (1,200), the LKT 111 polypeptide
(52,000) and the LKT 352 polypeptide (100,000), the
percentages of GnRH in the LKT-GnRH antigen fusions are
as follows: 4.9% (LKT 352::4 copy GnRH); 8.5% (LKT 111::4
35 copy GnRH); 9.3% (LKT 352::8 copy GnRH) and 15.7% (LKT

111::8 copy GnRH). Accordingly, the practical result thus obtained indicates that by using LKT-GnRH fusions comprising the LKT 111 polypeptide carrier, the overall amount of antigen (LKT-GnRH) administered to the subject
5 may be halved (as compared to vaccination compositions using the LKT 352 carrier polypeptide system) to obtain an equivalent anti-GnRH response.

Example 9

Prediction of T-cell Epitopes in the Recombinant
LKT 352 and LKT 111 Molecules

5 In order to predict potential T-cell epitopes
in the leukotoxin polypeptide sequences employed in the
LKT-GnRH chimeras of the present invention, the method
proposed by Margalit and co-workers (Margalit et al., *J.*
Immunol (1987) 138:2213) was performed on the amino acid
10 sequence corresponding to numbers 1 through 199 of the
LKT molecule as depicted in Table 4. Under the subject
method, the amino acid sequence of the leukotoxin
polypeptide sequence was compared to other sequences
known to induce a T-cell response and to patterns of
types of amino acids which are believed to be required
15 for a T-cell epitope. The results of the comparison are
depicted in Table 4.

As can be seen by the predictive results thus
obtained, there are several short sequences in the
leukotoxin peptide which are identified as potential T-
20 cell epitopes using the criteria suggested by Margalit et
al (supra). More particularly, 9 sequences were
identified as having a (Charged/Gly - Hydrophobic -
Hydrophobic - Polar/Gly) sequence (indicated as pattern
"1" in Table 4), and 3 sequences were identified as
25 having a (Charged/Gly - Hydrophobic - Hydrophobic -
Hydrophobic/Pro - Polar/Gly) sequence (indicated as
pattern "2" in Table 4). By coupling these data with the
in vivo anti-GnRH activity produced by both the LKT 352
and the LKT 111 carrier systems in Examples 7 and 8
30 above, it is indicated that critical T-cell epitopes are
retained in the shortened LKT 111 molecule, and that
those epitopes are likely contained within the N-terminal
portion of the LKT 352 and LKT 111 molecules.

35

D. Industrial Applicability

The leukotoxin-GnRH chimeras of the present invention are of use in providing immunogens that, when administered to a vertebrate host, serve to immunize the host against endogenous GnRH, which in turn acts to inhibit the reproductive function or capability of the host.

Notwithstanding the specific uses exemplified in this specification, the novel chimeric molecules disclosed herein suggest a means for providing fusion proteins comprising more than one GnRH peptide sequence, occurring in either multiple or tandem repeats, which are fused to immunogenic epitopes supplied by the leukotoxin polypeptide portion of the molecule (and in some cases by spacer peptide sequences occurring between selected GnRH sequences). The subject chimeric proteins constructed under the present invention provide enhanced immunogenicity to the fused GnRH peptide sequences, allowing an immunized vertebrate host to mount an effective immune response toward endogenous GnRH; effecting an interruption in the synthesis and release of the two gonadotropic hormones, luteinizing hormone (LH) and follicle stimulating hormone (FSH) and rendering the host temporarily sterile. In this manner, the novel leukotoxin-GnRH constructs may be employed in immunosterilization vaccines to provide an alternative to invasive sterilization procedures currently practiced in domestic and farm animal husbandry.

Other contemplated uses of the instant fusion molecules include population control, for example the interruption of reproduction capabilities in wild rodent populations. In this regard, the LKT-GnRH fusion molecules may be used as an alternative to population control measures currently practiced, such as poisoning and the like. The fusion products of the instant

invention may also be administered in constructs having both slow and fast release components. In this manner, the need for multiple vaccinations may be avoided. Further, since the amino acid sequence of GnRH is highly conserved among species, a single leukotoxin-GnRH fusion vaccine product may be produced which will exhibit broad cross species effectiveness.

Thus, various chimeric proteins comprising leukotoxin fused to selected GnRH polypeptides have been disclosed. Although preferred embodiments of the subject invention have been described in some detail, it is understood that obvious variations can be made without departing from the spirit and the scope of the invention as defined by the appended claims.

Deposits of Strains Useful in Practicing the Invention

A deposit of biologically pure cultures of the following strains was made with the American Type Culture Collection (ATCC), 12301 Parklawn Drive, Rockville, Maryland. The accession number indicated was assigned after successful viability testing, and the requisite fees were paid. The deposits were made under the provisions of the Budapest Treaty on the International Recognition of the Deposit of Microorganisms for the Purpose of Patent Procedure and the Regulations thereunder (Budapest Treaty). This assures maintenance of viable cultures for a period of thirty (30) years from the date of deposit and at least five (5) years after the most recent request for the furnishing of a sample of the deposit by the depository. The organisms will be made available by the ATCC under the terms of the Budapest Treaty, which assures permanent and unrestricted availability of the cultures to one determined by the U.S. Commissioner of Patents and Trademarks to be entitled thereto according to 35 USC §122 and the

Commissioner's rules pursuant thereto (including 37 CFR §1.12).

These deposits are provided merely as convenience to those of skill in the art, and are not an admission that a deposit is required under 35 USC §112. The nucleic acid sequences of these plasmids, as well as the amino acid sequences of the polypeptides encoded thereby, are incorporated herein by reference and are controlling in the event of any conflict with the description herein. A license may be required to make, use, or sell the deposited materials, and no such license is hereby granted.

<u>Strain</u>	<u>Deposit Date</u>	<u>ATCC No.</u>
P. haemolytica serotype 1 B122	February 1, 1989	53863

Claims:

1. A chimeric protein comprising a leukotoxin polypeptide fused to a multimer consisting essentially of more than one selected GnRH polypeptide, whereby said leukotoxin portion of said chimeric protein acts to increase the immunogenicity of said GnRH multimer.
2. The chimeric protein of claim 1 wherein said leukotoxin polypeptide lacks leukotoxic activity.
3. The chimeric protein of claim 2 wherein said leukotoxin is LKT 352.
4. The chimeric protein of claim 2 wherein said leukotoxin is LKT 111.
5. The chimeric protein of claim 1 wherein said GnRH multimer comprises a molecule according to the general formula GnRH-X-GnRH wherein X is selected from the group consisting of a peptide linkage, an amino acid spacer group, a leukotoxin polypeptide and $[\text{GnRH}]_n$ where n is greater than or equal to 1, and further wherein GnRH comprises any GnRH polypeptide.
6. The chimeric protein of claim 5 wherein X comprises an amino acid spacer group including at least one helper T-cell epitope.
7. The chimeric protein of claim 1 wherein said chimeric protein comprises the amino acid sequence depicted in Figure 5, or an amino acid sequence substantially homologous and functionally equivalent thereto.

8. The chimeric protein of claim 1 wherein said chimeric protein comprises the amino acid sequence depicted in Figure 7, or an amino acid sequence substantially homologous and functionally equivalent thereto.

9. A vaccine composition comprising the chimeric protein of any of claims 1-8 and a pharmaceutically acceptable vehicle.

10. A method for presenting a selected GnRH multimer to a subject comprising administering to said subject an effective amount of a vaccine composition according to claim 9.

11. A DNA construct encoding the chimeric protein of any of claims 1-8.

12. An expression cassette comprised of:
(a) the DNA construct of claim 11; and
(b) control sequences that direct the transcription of said construct whereby said construct can be transcribed and translated in a host cell.

13. A host cell transformed with the expression cassette of claim 12.

14. A method of producing a recombinant polypeptide comprising:
(a) providing a population of host cells according to claim 13; and
(b) culturing said population of cells under conditions whereby the polypeptide encoded by said expression cassette is expressed.

SUBSTITUTE SHEET (RULE 26)

INTERNATIONAL SEARCH REPORT

International Application No.
PCT/CA 96/00049

A. CLASSIFICATION OF SUBJECT MATTER

IPC 6 C12N15/62 C07K19/00 C07K7/23 A61K38/09 A61K39/385

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

IPC 6 C12N C07K A61K

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	WO,A,93 08290 (UNIV SASKATCHEWAN) 29 April 1993 cited in the application see page 4, line 11 - line 12 see page 8, line 2 - line 3 ---	1-14
Y	VACCINE, vol. 12, no. 8, June 1994, GUILDFORD GB, pages 741-746, XP000570334 MELOEN R.H. ET AL.: "Efficient immunocastration of male piglets by immunoneutralization of GnRH-like peptide" cited in the application see page 741, column 2 see page 742, column 1 see page 743, column 2 see Discussion --- -/-	1-14

☒ Further documents are listed in the continuation of box C.

☒ Patent family members are listed in annex.

* Special categories of cited documents :

- * A* document defining the general state of the art which is not considered to be of particular relevance.
- * E* earlier document but published on or after the international filing date
- * L* document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- * O* document referring to an oral disclosure, use, exhibition or other means
- * P* document published prior to the international filing date but later than the priority date claimed

- * T* later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
- * X* document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
- * Y* document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.
- * &* document member of the same patent family

Date of the actual completion of the international search

17 May 1996

Date of mailing of the international search report

07.06.96

Name and mailing address of the ISA

European Patent Office, P.B. 5818 Patentlaan 2
